

WHO/Statement WHO WELCOMES **INTERNATIONAL TREATY ON MERCURY** The World Health Organization (WHO) today welcomes the approval of a **new international convention**

* that will

reduce the harmful health effects of mercury

Mercury is recognized as a chemical of global concern due to its ability to travel long distances in the atmosphere; its persistence in the environment; its ability to accumulate in ecosystems, including in fish, and its significant negative effect on human health and the environment.

Mercury can produce a range of adverse human health effects, including permanent damage to the nervous system, in particular the developing nervous system. Due to these effects - and also because mercury can be passed from a mother to her unborn child, infants - children and women of child-bearing age are considered vulnerable populations. Agreement on the treaty followed extensive analysis of evidence and a series of high level intergovernmental negotiations involving more than 140 countries.

The final treaty negotiations occurred this week in Geneva and concluded today. The treaty establishes a number of protective measures, including controls on mercury emissions from coal-fired power plants and industry, as well as the use of mercury in artisanal and small scale gold mining, which are the major sources of mercury in the environment. The treaty also includes an article dedicated to health. In particular, the treaty sets a phase out date of 2020 for mercury thermometers and blood pressure measuring devices used in health care.

This adds support to WHO's programme assisting countries to replace these mercury devices with non-mercury alternatives. WHO also supports the treaty's "phasing-down" of the use of dental amalgam (a compound of mercury and silver-based alloys). This action will contribute to a reduction of mercury use and the risk of release to the environment. An important exception that was strongly supported in the negotiations was the use of thiomersal (ethyl-mercury) as a preservative in human and animal vaccines.

WHO has closely monitored scientific evidence relating to the use of thiomersal as a vaccine preservative for more than 10 years, through its Global Advisory Committee on Vaccine Safety, and the Committee has consistently concluded that there is no evidence to suggest that the amount of thiomersal used in vaccines poses a health risk. *The Minamata Convention on

Mercury For more on the Convention, see: <http://www.unep.org/newscentre/Default.aspx?DocumentID=2702&ArticleID=9373&l=en>

Note to editors Mercury releases in the environment result mainly from human activity, particularly from coal-fired power stations, residential coal burning for heating and cooking, industrial processes, waste incinerators and as a result of mining for mercury, gold and other metals.

Mercury is also released from volcanic activity and weathering of rocks. Almost 50 % of mercury emissions to air are from coal fired power plants, industrial boilers and household burning of coal.

Once in the environment, elemental mercury is naturally transformed into methylmercury that bioaccumulates in fish and shellfish. Methylmercury exposure in the womb, which can result from a mother's consumption of fish and shellfish that contain methylmercury, can adversely affect a baby's growing brain and nervous system, impacting on cognitive thinking, memory, attention, language, and fine motor and visual spatial skills.
