

- Tuberculosis could be fought more effectively with future drugs – thanks to new research into an old antibiotic by University of Warwick and Francis Crick Institute
- Deeper understanding of how simple but effective drug *D-cycloserine* attacks bacteria opens up possibility of development of new, desperately needed antibiotic drugs
- Bacterial infections are becoming increasingly resistant to drugs – new drugs needed to curb this deadly global crisis

Tuberculosis, and other life-threatening microbial diseases, could be more effectively tackled with future drugs, thanks to new research into an old antibiotic by the University of Warwick and The Francis Crick Institute.

Led by Professor David Roper at Warwick's School of Life Sciences and Dr Luiz Pedro Carvalho from The Francis Crick Institute, a paper published today in *Nature Communications*

reveals a deeper understanding of how the antibiotic *D-cycloserine* uniquely works at a molecular level.

rev

This could lead to more effective future antibiotics – which are desperately needed to fight increasingly drug-resistant and deadly bacteria.

D-cycloserine is an old antibiotic drug which is effective against many microbial diseases such as tuberculosis, but is often used as a second line treatment, because of some adverse side-effects.

The researchers have now discovered that it acts chemically in very different ways on multiple bacterial targets – possibly the only antibiotic in the world to do so.

The drug attacks bacteria by inhibiting two separate enzymes (*D-alanine racemase* and *D-alanine—D-alanine ligase*) each required to build and maintain the structural integrity of bacterial cell walls.

With the *D-alanine racemase* enzyme, it is known that the drug forms a molecular bond with a chemical group required for the enzyme activity, stopping it from working.

The researchers have observed, for the first time, how *D-cycloserine* inhibits the *D-alanine-D-alanine ligase* enzyme.

[David Roper, who is Professor of Biochemistry and Structural Biology](#) at the University Warwick, commented:

“In this new discovery, we see that D-cycloserine binds to the *D-alanine-D-alanine ligase* enzyme and becomes chemically modified on the enzyme. The chemical species formed here has never been seen before.

“We now understand fully how this antibiotic drug can have totally different methods of working on separate targets. This appears to be a unique amongst the antibiotics.”

Dr Luiz Pedro Carvalho, from the [Mycobacterial Metabolism and Antibiotic Research Laboratory](#) at the Francis Crick Institute, said:

“Perhaps more important than how *D-cycloserine* works, this study highlights an increasingly obvious fact: we know much less than we think about how antibiotics really work and how bacteria become resistant.

“Only by truly understanding molecular and cellular events caused by antibiotics or in response to their presence will we truly understand how to make improved drugs, which are much needed in face of the current threat of antibiotic resistance.”

New TB drugs possible with understanding of old antibiotic

A longer term goal will be to modify the structure of *D-cycloserine*, so that it more closely resembles the newly discovered chemical species, and in so doing produce an antibiotic that is more specific and avoids some of adverse side effects of *D-cycloserine*

—
enabling its wider use in the fight against antibiotic resistant infections.

There is a global crisis in healthcare because bacterial infections are becoming increasingly resistant to the antibiotic drugs we use to treat them.

Antimicrobial resistance threatens many aspects of human activity including medicine and agriculture and could lead to more deaths than cancer.
