### Results:

A total of 3030 participants were randomly assigned to the recommendation to wear masks, and 2994 were assigned to control; 4862 completed the study. Infection with SARS-CoV-2 occurred in 42 participants recommended masks (1.8%) and 53 control participants (2.1%). The between-group difference was  $-0.3$  percentage point (95% CI,  $-1.2$  to  $0.4$  percentage point;  $P = 0.38$ ) (odds ratio,  $0.82$  [CI,  $0.54$  to  $1.23$ ];  $P = 0.33$ ). Multiple imputation accounting for loss to follow-up yielded similar results. Although the difference observed was not statistically significant, the 95% CIs are compatible with a 46% reduction to a 23% increase in infection.
