

Surveillance of a novel norovirus variant

(Kawasaki, Japan, 16 February 2016) Genetic mutations that occurred in the norovirus GII.17 strains circulating in Japan from 2013 to 2015 were studied by researchers affiliated with Kawasaki

novation

G

ateway at SKYFRONT, Japan.

In their findings published in Euro Surveillance, the researchers call for careful monitoring of the new GII.17 variant to prevent global outbreaks due to the potential of it evading the host's immune system.

Further information about science and technology projects at Kawasaki City is available in the Kawasaki SkyFront iNewsletter that highlights research being conducted by scientists and industries affiliated with Kawasaki INnovation Gateway at SKYFRONT (**KING SKYFRONT**)—the City's flagship science and technology hub focused on open innovation in the life sciences and environment.

KING SKYFRONT is located on the opposite side of the Tama River that separates Tokyo International Airport (also known as Haneda Airport) and the Tonomachi district of Kawasaki. The Airport plays an important role in the globalization of the innovative activities of scholars, industrialists and City administrators based at KING SKYFRONT.

Surveillance of a novel norovirus variant

Norovirus is a major causative pathogen of viral gastroenteritis in people, leading to vomiting and diarrhea. Until recently, global outbreaks of norovirus have mainly been caused by genotype GII.4. However, a new variant norovirus strain was prevalent in Japan in the winter of 2014–2015. This novel norovirus was a genotype GII.17 variant.

To investigate the genetic mutations that have occurred in the norovirus GII.17 strains, Hideaki Shimizu and co-workers at the Kawasaki City Institute for Public Health, Kanagawa, and collaborating Japanese researchers conducted whole genome sequencing of the new variant including other GII.17 strains circulating in our country from 2013 to 2015 [1].

The team used next-generation sequencing techniques to analyse six GII.17 strains that were available in Japan from 2013 to 2015. All strains were assigned to GII.17 in the VP1 gene, which codes a major capsid protein of norovirus. However, the norovirus genotyping server could not characterize RNA polymerase genotypes of the strains, which indicates the norovirus contains novel sequences. Therefore, Shimizu and his team also inferred a potential of genetic mutations within the capsid region of the strains. They named the variant as Hu/GII/JP/2014/GII.P17-GII.17.

They found that the GII.17 strain circulating in Japan in November 2014 to March 2015 was a novel variant with several amino acid substitutions in the RNA polymerase and capsid regions.

Further phylogenetic analysis of norovirus shows the emergent strain has quietly been circulating in Asia from 2013. Also, it appears to undergo an evolutionary history diverse from other previous GII.17 strains.

The researchers call for careful monitoring of the new GII.17 variant, because it may trigger global outbreaks in future due to the potential to evade the host's immune system.

Researchers at the Kawasaki City Institute for Public Health identified the novel norovirus GII.17 variant, which caused a number of cases of acute gastroenteritis in Japan in winter 2014-2015, based on whole genome sequencing.

About KING SKYFRONT

The Kawasaki INnovation Gateway (KING) SKYFRONT is the flagship science and technology innovation hub of Kawasaki City. KING SKYFRONT is a 40 hectare area located in the Tonomachi area of the Keihin Industrial Region that spans Tokyo and Kanagawa Prefecture and Tokyo International Airport (also often referred to as Haneda Airport).

KING SKYFRONT was launched in 2013 as a base for scholars, industrialists and government administrators to work together to devise real life solutions to global issues in the life sciences and environment.
